

Below is the **opening chapter of the WeUP Shop Bible**, written as if this document is destined to become a **120+ page canonical text** used by designers, engineers, partners, artists, venues, and future governors of the system.

This is **not marketing copy**.

This is **philosophical infrastructure**—the axioms from which every commerce rule, smart contract, UI choice, and ethical boundary of the WeUP Shop will be derived.

I will begin **slow and deep**, exactly as a Bible should.

1. Philosophy of Event-Bound Commerce

Commerce has always followed gathering.

Before cities, markets formed where people met.

Before brands, objects carried meaning because of *where* and *with whom* they were exchanged.

Before platforms, value emerged from **presence**, not distribution.

The WeUP Shop exists to **restore this ordering**.

Not by nostalgia—but by system design.

Where modern commerce optimizes for:

- scale,
- infinite availability,
- frictionless extraction,

WeUP commerce is built around:

- **bounded time,**
- **situated meaning,**
- **earned access,**
- **shared witness.**

The WeUP Shop is not a store.

It is a **temporary economic field generated by an event**.

Events are not containers for commerce.

Commerce is a *byproduct* of convergence.

This principle echoes throughout the entire WeUP architecture, from ticketing to ritual design to post-event memory, and is consistent with the system's core thesis that **events are the atomic unit of value** .

1.1 Commerce as Presence

Presence is not attendance.

Attendance is binary: you were there or you were not.

Presence is *graded*, *situated*, and *felt*.

The WeUP Shop treats presence as a **first-class economic variable**.

Presence has dimensions:

- **Temporal**: how long you were there
- **Ritual**: how you participated
- **Social**: who you shared space with
- **Attentional**: what you gave your focus to
- **Contextual**: what the event itself represented

In traditional e-commerce, none of this exists.

A purchase is a click, abstracted from time, place, and meaning.

In WeUP:

- Some goods **cannot be purchased remotely**
- Some prices **change based on presence**
- Some items **do not appear unless presence thresholds are met**
- Some artifacts **exist only because you were witnessed acquiring them**

Presence becomes a **qualifier**, not a metric.

This aligns directly with WeUP's broader rejection of engagement-driven economies and its emphasis on *measurable presence* over attention harvesting .

Commerce as a shared act

In WeUP, buying is not isolated behavior.

Many WeUP Shop mechanics intentionally require:

- collective unlocks,

- synchronized moments,
- shared ritual completion,
- or crowd-level consensus.

This restores an ancient truth modern platforms erased:

Value is amplified when it is witnessed.

A WeUP purchase is often:

- something others were present for,
- something tied to a moment that cannot be replayed,
- something that only makes sense *because* of the event.

This is why WeUP commerce does not scale horizontally like Amazon.
It scales **vertically in meaning**.

1.2 Why Infinite Catalogs Destroy Meaning

Infinite catalogs promise freedom.

In reality, they produce:

- decision fatigue,
- emotional flattening,
- disposability,
- and cultural amnesia.

When everything is always available, nothing is *encountered*.

The tyranny of abundance

Modern commerce systems assume:

- more choice = more value,
- more availability = more convenience,
- more scale = more success.

WeUP rejects this premise at the architectural level.

The WeUP Shop enforces **scarcity by design**, not by artificial caps, but by:

- temporal boundaries,
- contextual relevance,

- eligibility constraints,
- and intentional disappearance.

An item that exists forever cannot hold memory.

An item that appears once can.

Scarcity as narrative, not manipulation

Traditional scarcity is often extractive:

- countdown timers,
- fake inventory limits,
- manufactured urgency.

WeUP scarcity is **ontological**.

Items are scarce because:

- the event ended,
- the ritual window closed,
- the collective threshold was not met,
- or the cultural moment passed.

This mirrors WeUP's broader resistance to infinite feeds and infinite availability across social and content systems .

Catalogs vs encounters

A catalog implies browsing.

An encounter implies *arrival*.

The WeUP Shop is structured so that:

- users rarely browse aimlessly,
- items appear when they are contextually meaningful,
- and disappearance is expected, not regretted.

The shop becomes a **storytelling surface**, not a warehouse.

1.3 Events as Economic Singularities

An event is not a backdrop.

In WeUP, an event is an **economic singularity**: a temporary zone where normal rules of access, value, and exchange are suspended and rewritten.

What makes an event a singularity

During an event:

- time is bounded,
- identity is contextual,
- social graphs temporarily reorganize,
- attention is synchronized,
- and meaning density spikes.

The WeUP Shop leverages this compression.

Instead of stretching commerce across infinite time, it **collapses value into moments**.

Event gravity

Events in WeUP generate *economic gravity*.

This gravity:

- pulls in vendors, artists, and sponsors,
- shapes what goods can exist,
- determines who can access them,
- and governs how value flows afterward.

Once the event ends, gravity dissipates—but it leaves **residual artifacts**:

- memory objects,
- lineage markers,
- access tokens,
- and cultural receipts.

This is consistent with WeUP's event-first system architecture and its treatment of post-event artifacts as first-class outputs of participation .

Why this matters long-term

When events are treated as singularities:

- commerce cannot become extractive without collapsing the event itself,
- over-monetization is self-limiting,
- and cultural trust becomes economically protected.

This is why the WeUP Shop can support:

- artists without commodifying them,
- sponsors without polluting space,
- vendors without turning gatherings into malls.

The event governs commerce—not the other way around.

Closing Frame for Chapter 1

Most platforms ask:

How do we sell more things to more people?

WeUP asks:

What value is allowed to exist in this moment?

This chapter establishes the **moral geometry** of the WeUP Shop.

Everything that follows—

ritual-gated items, ghost shops, lineage artifacts, presence-weighted pricing, residual economies—

is simply a **logical consequence** of these first principles.

Next chapters will expand into:

- **Temporal shop models**
- **Artifact ontologies**
- **Pricing mechanics**
- **Ritual economies**
- **Vendor and artist systems**
- **Sponsor ethics**
- **Post-event economic afterlife**

Each chapter will deepen, not widen.

When you're ready, the next section would naturally be:

2. Temporal Architecture of the WeUP Shop

(How time itself becomes a design material for commerce)

2. Shop Types & Temporal Models

If **presence** is the *why* of WeUP commerce, **time** is the *physics*.

Traditional commerce systems assume a static marketplace: a permanent shelf, an always-on cart, a timeless catalog. WeUP assumes the opposite: **value is phase-dependent**. The shop is a *field* that forms when an event forms, intensifies when the event goes live, and collapses when the moment passes—leaving behind only what the event legitimately earned: artifacts, receipts, and residual rights.

This chapter defines the canonical **shop types** as **temporal state machines** (formal, implementable models), and ties each to the blockchain stack you’ve already declared as foundational: **Stellar for payouts/settlement and Soroban for contract logic**, with **Solana-style high-throughput programs/VRFs** as an optional acceleration layer for certain mechanics (auctions, randomized allocations, high-frequency drop events).

2.0 Temporal Axioms (Formal Model)

Let an event be (E), with:

- Start time (t_s)
- End time (t_e)
- A set of discrete **phases** ($\Phi = \{\phi_0, \phi_1, \dots, \phi_n\}$) with boundaries ($t_0 < t_1 < \dots < t_n$)
- A shop instance (S_E) bound to (E)

We define a **shop availability function**:

$$\begin{bmatrix} A_S(t) \in \{0,1\} \end{bmatrix}$$

and a **visibility function** (tier/lineage/eligibility constrained):

$$\begin{bmatrix} V_S(u, t) \in \{0,1\} \end{bmatrix}$$

where (u) is an identity (pseudonymous user identity, optionally wallet-bound).

A purchasable item (i) has a **validity window** ($[t_{i,open}, t_{i,close}]$) and an eligibility predicate:

$$[\text{Eligible}(u, i, t) = \mathbf{1}[V_S(u,t)=1 \wedge t \in [t_{i,\text{open}}, t_{i,\text{close}}] \wedge C(u,i,t)]]$$

where $(C \cdot)$ encodes constraints like attendance proof, ritual completion, invite lineage, geo-fence, etc.

On-chain, the canonical anchor is not “the shop UI.” It’s a set of **commitments and receipts**:

- **Commitments** (hashes of offers, inventories, allocation seeds, rule sets) published before windows open
- **Receipts** (purchase proofs + fulfillment obligations) minted/recorded when the purchase occurs
- **Settlements** (payout splits to venue/vendor/artist/sponsor/lineage) executed deterministically after close

This is how WeUP stays scientifically honest: **time-dependent behavior is not hand-wavy UX**—it’s formalized in predicates and verified via commitments and receipts.

2.1 Live Event Shops

Definition

A **Live Event Shop** exists only while the event is in its live window:

$$[A_S(t) = 1 \quad \text{iff} \quad t \in [t_s, t_e]]$$

Live shops are the “high-pressure zone” where presence has maximum meaning density.

Core Mechanics

- **Attendance-gated access:** you must possess an *entry proof* (ticket validation or check-in receipt) to see or buy certain items.
- **Ritual-gated unlocks:** items appear only after ritual thresholds or synchronized moments.
- **Time-sliced inventory:** drops occur at (t_k) for $k=1..m$, not continuously.
- **Anti-hoarding constraints:** per-identity quotas, decay-based restocks, and transfer limits.

Blockchain Integration (Stellar + Soroban)

Soroban (contract logic):

- Represent each Live Shop drop as a contract state with:
 - rule hash (h_r)
 - inventory commitment (h_l) (e.g., Merkle root of SKU list + quantities)
 - optional allocation seed commitment (h_\sigma)

Stellar (settlement):

- Purchases create a **Work Receipt** (off-chain signed payload + optional on-chain hash anchor).
- Funds route via:
 - **Stellar escrow** (held until event close)
 - deterministic split to:
 - venue wallet
 - vendor wallet
 - artist wallet
 - sponsor wallet (if applicable)
 - lineage wallets (if WeUP enables residual lineage share)

This yields a clean “physics”:

- **Soroban enforces rules**
- **Stellar moves money**
- Receipts prove what happened, even if the buyer later goes offline

Scientific/Operational Note

Live shops must tolerate poor connectivity. Therefore, WeUP uses **two-phase commerce**:

1. **Authorize**: identity signs intent (or wallet signs) + POS (point-of-sale) generates a local receipt
2. **Settle**: receipt is later anchored and paid out on Stellar when connectivity returns

This is robust and falsifiable: every settlement corresponds to a receipt hash.

2.2 Pre-Event Anticipation Shops

Definition

A **Pre-Event Anticipation Shop** is active in a window leading into the event:

$$[A_S(t) = 1 \quad \text{iff} \quad t \in [t_p, t_s)]$$

where (t_p) is the pre-open time.

These shops are for **pre-commitment**, **pre-order**, and **anticipation artifacts**—without diluting the live moment.

Core Mechanics

- **Reservation without fulfillment** (preorders that can't be “used” until presence is proven)
- **Deposits / holds** tied to attendance
- **Limited “pre-flight” inventory**: items that set narrative or equip the attendee (wearables, passes, ritual objects)

Blockchain Integration

Commit–Reveal Fairness (Soroban / optional Solana VRF):

- If the system allocates scarce pre-event inventory (e.g., 100 “front-row access objects”), fairness requires public auditability.
- WeUP publishes:
 - commitment ($h_\sigma = H(\sigma)$) before allocation
 - later reveals seed (σ) and uses deterministic selection
- If you need stronger unpredictability, a **VRF** (Verifiable Random Function) is appropriate. Solana ecosystems commonly use VRF-style oracles; WeUP can adopt that pattern where high-throughput randomness is required. The key is: **selection must be verifiable**, not “trust us.”

Stellar Deposits / Escrow:

- Preorders place funds into escrow with rules:
 - if attendance is proven by (t_e), funds settle normally
 - if no attendance, refund or convert to a different artifact class (policy-defined)

This creates a sane incentive system: people don't hoard “maybe-attend” inventory without cost.

Scientific/Operational Note

Pre-event commerce must not become a substitute for attending. Therefore, WeUP enforces:

[
 $\text{Utility}(i) \rightarrow 0 \quad \text{without presence proof}$
]

Meaning: the most meaningful artifacts either cannot be redeemed or remain inert without actual attendance.

2.3 Post-Event Residual Shops

Definition

A **Post-Event Residual Shop** opens after the event:

[
 $A_S(t) = 1 \quad \text{iff} \quad t \in (t_e, t_r]$
]

where (t_r) is the residual close time (finite by design).

Residual shops are the event's "afterlife": not infinite monetization, but **cultural residue** and **settlement tail**.

Core Mechanics

- **Claim windows** for attendees (redeemable artifacts, proofs, media)
- **Delayed drops** tied to post-event processing (photos, mixes, recordings)
- **Residual access** for vendors to fulfill orders or resolve disputes
- **Memory objects** that encode what happened, not what's trending

Blockchain Integration

Deterministic Payout Finalization (Stellar):

- Residual period is when final numbers are known:
 - attendance
 - refunds
 - chargebacks
 - vendor fulfillment confirmations
- Payout function:

[
 $P_j = \alpha_j \cdot R_{\{\text{net}\}}$
]

where (R_{net}) is net revenue and (α_j) are share coefficients that sum to 1 (venue/vendor/artist/sponsor/lineage pools).

This is where Stellar shines: cheap, reliable, transparent settlement.

Soroban: Dispute & Settlement State

- Contract keeps minimal state:
 - pending receipts root
 - fulfilled/unfulfilled flags
 - dispute timers
 - finalization conditions

Scientific/Operational Note

Residual windows are intentionally bounded to avoid the “infinite catalog trap.” The residual shop is a **decaying tail**, not a permanent storefront:

$$\begin{aligned} &[\\ &A_S(t) \xrightarrow[t \rightarrow \infty]{} 0 \\ &] \end{aligned}$$

2.4 Ghost & Shadow Shops

These are the most WeUP-native shop forms because they make visibility itself part of the economy.

Shadow Shop (Definition)

A **Shadow Shop** exists in real time but is visible only to eligible identities:

$$\begin{aligned} &[\\ &V_S(u,t) = 1 \quad ;: \text{only if} \quad ;: u \in \mathcal{E}(t) \\ &] \end{aligned}$$

where $(\mathcal{E}(t))$ is an eligibility set derived from tier, lineage, ritual status, or role.

Shadow shops are how WeUP supports:

- sponsor activations without pollution
- VIP or role-specific gear (artist tools, vendor supplies)
- underground discretion (invite-only commerce)

Ghost Shop (Definition)

A **Ghost Shop** is **not visible during the event**, and may only appear after:

[
A_S(t)=1 ;\text{only if}; t > t_e \quad \text{and} \quad \mathrm{Proof}(u,E)=1
]

Ghost shops are for:

- post-event “you had to be there” artifacts
- memory drops
- delayed ritual rewards
- redemption of hidden items “found” during the event

Blockchain Integration

Privacy-Preserving Eligibility (Soroban + off-chain proofs):

WeUP must avoid doxxing or exposing “who had access.” Practical approach:

- Store **eligibility commitments** on-chain (e.g., Merkle root of eligible identity hashes).
- User proves membership with a Merkle proof without revealing the full list.

Formally:

- publish root ($R = \mathrm{MerkleRoot}(\{H(u_1), \dots, H(u_n)\})$)
- user provides proof path (π) such that verification passes:
[
 $\mathrm{VerifyMerkle}(H(u), \pi, R)=1$
]

This is mathematically standard and auditable.

Shadow pricing / lineage splits (Stellar):

Shadow/ghost items often drive lineage economics (residual shares to invite owners). Stellar payout graph can include lineage wallets as recipients with coefficients.

Scientific/Operational Note

Ghost and Shadow Shops are where WeUP can be *strictly more private* than mainstream commerce while still remaining verifiable. The trick is committing to sets and rules, not exposing identities.

2.5 Recursive Event Shops

Definition

A **Recursive Event Shop** is a shop whose artifacts or rights propagate into future events.

Let (E_k) be an event sequence. A purchase in (E_k) can create a stateful object (o) that modifies eligibility for (E_{k+1}) (or later):

[
o $\in \mathcal{O}(E_k) \rightarrow \text{Eligible}(u, E_{k+m}) \text{ changes}$
]

This is how WeUP evolves from “selling items” into “designing cultural continuity.”

Core Mechanics

- **Access objects** (future entry rights)
- **Ritual seeds** (unlock rituals in later events)
- **Vendor continuity passes** (preferred placement rights)
- **Artist arc artifacts** (multi-event narrative items)
- **Lineage reinforcement** (strengthening an invite subtree)

Blockchain Integration

Soroban: Stateful Rights Objects

- Represent recursive objects as non-transferable rights (or restricted-transfer tokens).
- Store:
 - issuer event id hash
 - scope (what future events it affects)
 - expiry
 - revocation policy

Stellar: Multi-Event Settlement

- For “residual ownership,” you can implement **rolling revenue shares** where a subset of revenue from (E_{k+m}) is allocated to holders of rights minted at (E_k) .
- This is a governance decision, but the math is straightforward:
[
 $P_{\{\text{rights}\}}(E_{k+m}) = \beta \cdot R_{\{\text{net}\}}(E_{k+m})$
]
distributed across eligible rights holders by rules (equal, weighted by tier, weighted by lineage depth, etc.).

Scientific/Operational Note

Recursive shops must be tightly controlled to avoid speculative markets. The guardrails are:

- non-transferability (or strict transfer rules)
 - explicit expiry
 - revocation for abuse
 - bounded scope (“this affects 2 future events, not your entire life”)
-

Chapter 2 Closing Frame

Time is not a UI detail in WeUP.

Time is a **cryptographically enforceable boundary**:

- what exists,
- who can see it,
- when it can be claimed,
- and how value flows afterward.

This is how WeUP avoids the two universal commerce failures:

1. **infinite catalog meaning-collapse**, and
 2. **extractive monetization that destroys the event**.
-

Next logical section (Chapter 3)

3. Goods, Artifacts & Cultural Objects

3.1 Physical Artifacts

3.2 Digital Artifacts

3.3 Hybrid Objects

3.4 Ritual Objects

3.5 Memory Objects

That chapter is where we define the **artifact ontology** (data model + contract model), and the “WeUP-native object classes” that vendors, artists, and sponsors will build against.

Below is **Chapter 3 of the WeUP Shop Bible**, written as **internal doctrine + implementable system spec**.

This chapter defines **what kinds of things are allowed to exist** inside WeUP commerce, and—more importantly—**what they are allowed to do over time**.

This is where meaning becomes **data**, and objects become **stateful participants** in the WeUP economy.

3. Goods, Artifacts & Cultural Objects

In conventional commerce, a “product” is inert. It has a SKU, a price, and an inventory count. Once sold, it exits the system.

In WeUP, objects **do not exit**—they **transition**.

Every WeUP object is modeled as a **stateful cultural artifact** with:

- an origin event,
- a lifecycle,
- eligibility rules,
- and downstream effects on access, reputation, or memory.

Formally, any object (o) in WeUP is defined as a tuple:

[
 $o = (E_o, T_o, \Sigma_o, \mathcal{C}_o, \mathcal{L}_o)$
]

Where:

- (E_o) = originating event
- (T_o) = object type
- (Σ_o) = internal state (mutable or immutable)
- $(\mathcal{C}_o)$ = constraints (eligibility, transferability, activation)
- $(\mathcal{L}_o)$ = lifecycle function over time

This abstraction applies equally to physical goods, digital media, ritual tokens, and memory artifacts.

3.1 Physical Artifacts

Definition

A **Physical Artifact** is a materially embodied object whose **economic meaning** is inseparable from its originating event.

Examples:

- apparel worn at the event
- instruments, posters, books, prints
- handcrafted objects
- limited-run merchandise tied to time/place

System Model

Physical artifacts are modeled as **off-chain objects with on-chain identity anchors**.

Let:

- (p) be a physical artifact
- $(h_p = H(\text{metadata}_p))$ be a cryptographic commitment to its origin

The system stores:

- (h_p) (hash of event ID + item class + run ID)
- fulfillment obligations
- optional ownership receipt

This creates **verifiable provenance** without forcing NFTs onto every physical good.

Business Logic

- Physical artifacts **must** reference an originating event (E_o)
- Inventory is finite and time-bounded
- Fulfillment is escrowed:
 - funds held until vendor confirms shipment
 - disputes resolved during residual window
- Optional linkage:
 - scanning a QR/NFC tag later can unlock digital memory or access

Why This Matters

Physical goods gain **secondary meaning** because:

- they prove attendance,
- they anchor memory,
- and they can unlock future states (e.g., early access at later events).

In WeUP, a shirt is never “just merch.”

It’s a **witnessed object**.

3.2 Digital Artifacts

Definition

A **Digital Artifact** is a non-physical object whose **value derives from context, not reproducibility**.

Examples:

- recordings, mixes, photos
- digital art
- access passes
- post-event media bundles
- artist statements or unreleased works

Mathematical Model

A digital artifact (d) is governed by a **validity and access function**:

$$\left[\begin{array}{l} \mathrm{Access}(u, d, t) = \mathbf{1}[\mathrm{Proof}(u, E_o)=1 \wedge t \in \mathcal{W}_d] \\ \end{array} \right]$$

Where:

- $(\mathcal{W}_d)$ is the access window
- Proof may be attendance, lineage, ritual completion, or role

Blockchain Integration

- Soroban contract encodes:
 - access rules
 - revocation/expiry
 - non-transferability flags
- Stellar anchors:
 - payment receipts
 - royalty splits for creators

No speculative resale is permitted by default.

Transferability, if allowed, is **explicitly declared**.

Business Logic

- Digital artifacts are often:
 - delayed (released days or weeks later)

- gated (only attendees, only certain tiers)
 - decaying (access expires)
- Revenue:
 - direct purchase
 - bundled with attendance
 - sponsor-subsidized free drops

This protects artists from infinite redistribution while preserving accessibility.

3.3 Hybrid Objects

Definition

A **Hybrid Object** exists simultaneously in physical and digital form, with **cross-linked state**.

Examples:

- physical items that unlock digital content
- digital passes redeemable for physical artifacts
- wearables tied to post-event media
- books, vinyl, posters with embedded access

System Model

Hybrid objects introduce a **bi-modal state**:

```
[
\Sigma_o = (\Sigma_{phys}, \Sigma_{dig})
]
```

Activation in one domain modifies the other.

Example:

- scanning the physical artifact flips a digital flag
- redeeming digital access may invalidate a physical claim

Blockchain Role

- Physical side: off-chain fulfillment + identity anchor
- Digital side: Soroban enforces one-time activation or limited activations
- Stellar handles split payouts across vendors and creators

Business Logic

- Prevents counterfeiting and duplication
- Encourages long-term engagement
- Allows phased value delivery (before, during, after event)

Hybrid objects are **WeUP's bridge between atoms and bits**.

3.4 Ritual Objects

Definition

A **Ritual Object** is an artifact whose **primary function is behavioral**, not consumptive.

It exists to:

- guide attention
- coordinate action
- or mark participation in a collective act

Examples:

- phone-lock tokens
- synchronized action prompts
- access keys unlocked only after ritual completion
- artifacts that activate only if a ritual succeeds

Formal Model

Let (R) be a ritual with completion function:

$$\begin{bmatrix} \mathrm{Complete}(R,t) \in \{0,1\} \end{bmatrix}$$

A ritual object (r_o) has activation:

$$\begin{bmatrix} \mathrm{Active}(r_o,t) = \mathrm{Complete}(R,t) \end{bmatrix}$$

System Enforcement

- Ritual success/failure is computed from:
 - aggregate participation
 - time-window compliance
 - optional device signals (privacy-preserving)
- Soroban contracts enforce activation logic
- No individual is punished; rewards are collective

Business Logic

- Ritual objects may:
 - unlock hidden shops
 - reduce prices
 - release memory artifacts
 - grant future access
- Sponsors may fund ritual rewards without branding pollution
- Failure is allowed; scarcity emerges naturally

This turns commerce into **coordination**, not distraction.

3.5 Memory Objects

Definition

A **Memory Object** is an artifact whose value emerges **only after the event has ended**.

Examples:

- post-event recordings
- curated photo sets
- narrative summaries
- “you were there” proofs
- anniversary reactivations

Mathematical Framing

Memory objects are defined by a **temporal inversion**:

$$[\mathrm{Value}(o,t) \uparrow \text{ as } |t - t_e| \uparrow]$$

Meaning: value increases with temporal distance from the event, not immediacy.

System Logic

- Memory objects are:
 - inaccessible during the event
 - unlocked after reflection
- Access often requires:
 - attendance proof
 - ritual participation
 - non-transferability

Business Logic

- Encourages delayed gratification
- Prevents live monetization overload
- Extends event's cultural half-life without infinite catalog creep

Memory objects are **cultural receipts**, not content spam.

Chapter 3 Closing Frame

In WeUP, objects are not inventory.

They are:

- **state machines**
- **witnesses**
- **contracts**
- **memories**
- **coordination tools**

This chapter defines the **ontology** that makes the WeUP Shop impossible to clone by traditional marketplaces. Others can sell products.

Only WeUP can sell **context-bound meaning**—because the system itself enforces it.

Next Chapter (Logical Continuation)

4. Access Control & Eligibility Logic

4.1 Tier-Locked Commerce

4.2 Attendance-Locked Inventory

4.3 Invite-Lineage Unlocks

4.4 Ritual Completion Gates

That chapter is where these objects meet **who is allowed to touch them, when, and why**—and where the invite tree, tiers, and cryptographic proofs become economically decisive.

Below is **Chapter 4 of the WeUP Shop Bible**, written as **system architecture + mathematical rigor + concrete user impact**.

This chapter is where philosophy turns into **enforcement**, and where commerce becomes *selective without being exclusionary*.

This is not just “who can buy what.”

This is **how culture protects itself at scale**.

4. Access Control & Eligibility Logic

Access is the invisible hand of WeUP commerce.

Most platforms treat access as binary:

- logged in / logged out
- paid / unpaid
- follower / non-follower

WeUP treats access as **contextual, earned, and time-dependent**.

Every WeUP Shop interaction passes through an **Eligibility Engine**—a deterministic system that evaluates *who, when, where, and under what conditions* a good may appear, activate, or settle.

At a system level, every purchase attempt evaluates:

$$\left[\mathrm{Eligible}(u, o, t) = \mathbf{1} \big[T(u) \wedge A(u, E) \wedge L(u) \wedge R(u, E, t) \big] \right]$$

Where:

- $T(u)$ = tier predicates
- $A(u, E)$ = attendance predicates
- $L(u)$ = lineage predicates
- $R(u, E, t)$ = ritual predicates

Each subsection below defines one axis of this eligibility space, including **backend services**, **contract logic**, and **frontend user flow**.

4.1 Tier-Locked Commerce

Concept

Tier-Locked Commerce restricts visibility and purchase rights based on a user's current WeUP tier (Inner / Mid / Outer, or future granular roles).

This is not a status flex.
It is **load-balancing culture**.

System Architecture

Identity & Tier Service

- Maintains:
 - user UUID
 - tier assignment
 - tier history (for audits)
- Emits tier-change events

Eligibility Engine

- Queries tier at request time
- Applies tier predicates to:
 - shop visibility
 - SKU visibility
 - pricing rules
 - quantity limits

Soroban Contracts

- Encode tier requirements as immutable predicates:
 - `minTier`
 - `maxTier`
 - optional tier-weighted allocation

Mathematical Model

Let tiers be partially ordered:

```
[  
T_1 \prec T_2 \prec T_3  
]
```

An item (o) defines:

```
[  
T_{\min}(o),; T_{\max}(o)  
]
```

Eligibility condition:

```
[  
T_{\min}(o) \leq T(u) \leq T_{\max}(o)  
]
```

User Impact & Flow

User Experience

1. User opens event page
2. Shop UI renders *tier-aware*
 - some items visible
 - others hidden (not greyed out by default)
3. If user upgrades tier later:
 - new items *appear* retroactively
4. No “you’re not allowed” shaming

Why This Works

- Prevents overcrowding of sensitive goods
- Rewards trust without public leaderboards
- Keeps high-signal artifacts from being diluted

Tier-locking is *quiet power*, not loud hierarchy.

4.2 Attendance-Locked Inventory

Concept

Some goods only exist **because you were there**.

Attendance-Locked Inventory requires **cryptographic proof of presence**, not screenshots, not self-reporting.

System Architecture

Attendance Proof Service

- Issues a verifiable receipt at check-in:
 - QR scan
 - NFC tap
 - offline signed receipt
- Receipt includes:
 - event hash
 - timestamp
 - anonymous user reference

Eligibility Engine

- Validates receipt existence
- Validates receipt freshness
- Applies to inventory unlock

Blockchain Anchoring

- Optional hash of receipt anchored on-chain
- Full receipt remains off-chain for privacy

Mathematical Model

Attendance predicate:

$$[A(u, E) = \mathbf{1}][\exists r \in \mathcal{R}_E(u)]$$

Where $(\mathcal{R}_E(u))$ is the set of valid attendance receipts.

User Impact & Flow

User Journey

1. User checks in at event
2. Attendance receipt generated silently
3. Shop UI updates in real time:
 - new SKUs appear
 - prices may change

4. Post-event:
 - some items remain accessible
 - others vanish forever

Psychological Effect

- Buying feels earned, not transactional
- Eliminates FOMO for non-attendees
- Strengthens “you had to be there” without elitism

Attendance-locked goods turn presence into **cultural currency**, not bragging rights.

4.3 Invite-Lineage Unlocks

Concept

In WeUP, **who invited you matters**—not socially, but structurally.

Invite-Lineage Unlocks allow commerce to recognize **relational trust chains**, not individual clout.

System Architecture

Invite Graph Service

- Directed acyclic graph (DAG):
 - nodes = identities
 - edges = invite relationships
- Depth, ancestry, and sibling sets computable

Eligibility Engine

- Evaluates lineage predicates:
 - direct inviter
 - ancestor depth
 - shared lineage clusters

Privacy Layer

- Lineage proofs can be:
 - explicit (off-chain graph query)
 - implicit (Merkle proof of membership in lineage set)

Mathematical Model

Let $(G = (V, E))$ be the invite DAG.

Define:

- $\text{depth}(u)$
- $\text{ancestor}(u, k)$

Eligibility condition example:

[
 $L(u) = \mathbf{1}[\text{ancestor}(u, k) \in S]$
]

Where (S) is a set of privileged lineage roots.

User Impact & Flow

User Experience

1. User enters event via invite
2. Certain items appear labeled subtly:
 - “shared circle”
 - “lineage release”
3. User may not even know *why* they see it
4. No public display of lineage status

Why This Matters

- Encourages thoughtful invitations
- Rewards cultural stewardship
- Prevents random viral growth from accessing sensitive goods

Lineage unlocks make commerce **relational**, not algorithmic.

4.4 Ritual Completion Gates

Concept

Some things should only exist **if the crowd earns them together**.

Ritual Completion Gates tie access to **collective behavior**, not individual action.

System Architecture

Ritual Engine

- Defines:
 - ritual phases
 - success criteria
 - time windows
- Collects anonymous participation signals

Aggregation Service

- Computes completion metrics:
 - % compliance
 - synchronization windows
- Emits success/failure state

Eligibility Engine

- Reacts to ritual state transitions
- Unlocks:
 - shops
 - SKUs
 - price changes
 - future access objects

Mathematical Model

Let ritual (R) have completion function:

$$[C_R(t) = \mathbf{1} \left[\frac{1}{N} \sum_{i=1}^N p_i(t) \geq \theta \right]]$$

Where:

- $(p_i(t))$ = participation signal (binary or weighted)
- (θ) = threshold

Eligibility:

$$[R(u, E, t) = C_R(t)]$$

User Impact & Flow

Live Event Flow

1. Ritual announced (opt-in)
2. Users participate (or not)
3. No individual tracking shown
4. If threshold met:
 - shop appears
 - hidden items unlock
 - prices drop
5. If threshold fails:
 - nothing breaks
 - nothing shames
 - scarcity emerges naturally

Why This Works

- Aligns commerce with attention
- Encourages collective responsibility
- Makes success feel shared

Ritual gates transform buying into **cooperation**, not competition.

Chapter 4 Closing Frame

Access in WeUP is not a wall.

It is a **filter that preserves signal**.

Every eligibility rule serves at least one of these goals:

- protect the event
- reward presence
- reinforce trust
- prevent extraction
- preserve meaning

By combining:

- tier logic,
- attendance proofs,
- lineage graphs,
- and ritual state machines,

WeUP achieves something rare:

Selective commerce that feels fair, not exclusionary.

Next Chapter (Natural Progression)

5. Pricing & Scarcity Systems

5.1 Time-Decay Pricing

5.2 Collective Unlock Pricing

5.3 Presence-Weighted Discounts

5.4 Scarcity Without Speculation

That chapter is where access meets **economic dynamics**—how prices move, why scarcity feels honest, and how WeUP avoids the psychological traps of traditional marketplaces.

Below is **Chapter 5 of the WeUP Shop Bible**.

This chapter formalizes **pricing as a dynamic system**, not a static number, and shows how WeUP engineers scarcity **without speculation, manipulation, or psychological dark patterns**.

This is where economics, systems design, and human behavior finally stop fighting each other.

5. Pricing & Scarcity Systems

Price is not a number.

Price is a **signal**—a compressed message about value, time, effort, trust, and consequence.

Traditional commerce treats price as:

- static,
- arbitrary,
- optimized for conversion.

WeUP treats price as a **field variable** that evolves with:

- time,
- presence,
- collective action,
- and ethical constraints.

Every WeUP price is computed, not declared.

Formally, for any object (o), the effective price at time (t) for user (u) is:

$$P(o,u,t) = P_0(o) \cdot f_t(t) \cdot f_p(u) \cdot f_c(E,t) \cdot f_s(o)$$

Where:

- $(P_0(o))$ = base price
- $(f_t(t))$ = time-based modifier
- $(f_p(u))$ = presence-based modifier
- $(f_c(E,t))$ = collective-state modifier
- $(f_s(o))$ = scarcity constraint

Each component is bounded, auditable, and explicitly declared in contract logic.

5.1 Time-Decay Pricing

Concept

Some things are most valuable **now**, not later.

Time-decay pricing acknowledges that immediacy carries meaning—and that hesitation has a cost.

System Architecture

Pricing Engine

- Computes price as a function of time since unlock
- Uses monotonic functions (no oscillation)
- Enforces floor and ceiling bounds

Soroban Contract

- Stores:
 - base price
 - decay function parameters
 - floor price
- Validates client-submitted prices against on-chain computation

Mathematical Model

A standard decay function:

```
[  
f_t(t) = \max(\alpha, e^{\{-\lambda(t - t_0)\}})  
]
```

Where:

- (λ) = decay rate
- (t_0) = unlock time
- (α) = minimum price ratio (floor)

This guarantees:

- price never hits zero
- no sudden drops
- predictable behavior

User Impact & Flow

User Experience

1. Item unlocks
2. UI shows:
 - current price
 - subtle “now / later” framing (no countdown panic)
3. Waiting is allowed—but meaning decays
4. No flash-sale manipulation

Why This Works

- Rewards decisiveness
- Removes artificial urgency
- Align pricing with lived experience

Time-decay pricing mirrors reality: moments pass.

5.2 Collective Unlock Pricing

Concept

Some prices should only drop **if the group succeeds**.

Collective unlock pricing ties cost reduction to **shared action**, not individual arbitrage.

System Architecture

Ritual Engine

- Emits completion state + participation ratio

Pricing Engine

- Applies discount only when ritual success event fires

Soroban Contract

- Encodes:
 - discount function
 - threshold
 - single-use or time-bound application

Mathematical Model

Let $(C_R(t))$ be ritual completion:

```
[  
f_c(E,t) =  
\begin{cases}  
1 & \text{if } C_R(t)=0 \\  
\beta & \text{if } C_R(t)=1  
\end{cases}  
\quad \text{where } 0 < \beta < 1  
]
```

User Impact & Flow

Live Event Flow

1. Ritual announced
2. Participation is opt-in
3. No individual progress bars
4. If success:
 - price drops for everyone
5. If failure:
 - nothing breaks
 - original price remains

Why This Works

- Prevents race-to-buy behavior
- Encourages cooperation
- Makes price drops feel earned, not gamed

Collective pricing transforms commerce into coordination.

5.3 Presence-Weighted Discounts

Concept

If you showed up, stayed, and participated—you should not pay the same as someone who barely appeared.

Presence-weighted pricing aligns **economic reward with lived engagement**.

System Architecture

Presence Index Service

- Computes a scalar ($\Pi(u, E) \in [0, 1]$)
- Inputs:
 - attendance duration
 - ritual participation
 - role-specific actions
- Privacy-preserving aggregation

Pricing Engine

- Applies bounded discount based on (Π)

Soroban Contract

- Verifies discount bounds
- Rejects forged presence claims

Mathematical Model

$$\begin{aligned}
 &[\\
 &f_p(u) = 1 - \gamma \cdot \Pi(u, E) \\
 &\quad \text{with } 0 \leq \gamma \leq \gamma_{\max} \\
 &]
 \end{aligned}$$

This ensures:

- no free items
- no extreme favoritism
- smooth gradation

User Impact & Flow

User Experience

1. User browses shop
2. Price shown already accounts for presence
3. No “points,” no leaderboards
4. The reward is subtle, not performative

Why This Works

- Rewards genuine engagement
- Avoids gamification fatigue
- Keeps pricing fair without public scoring

Presence becomes value—quietly.

5.4 Scarcity Without Speculation

Concept

Scarcity should reflect **real constraints**, not resale fantasies.

WeUP explicitly rejects speculative markets.

System Architecture

Scarcity Engine

- Tracks:
 - inventory caps
 - issuance rate
 - redemption state
- Enforces:
 - per-identity limits
 - non-transferability by default

Soroban Contract

- Encodes:
 - max supply
 - minting window
 - transfer rules (often disabled)

Stellar Settlement

- No secondary market routing
- No royalty extraction from resale unless explicitly enabled

Mathematical Constraints

Let total supply be ($S_{\max}$):

$$\left[\sum_u \mathrm{Issued}(o, u) \leq S_{\max} \right]$$

Transfer constraint:

$$\left[\begin{array}{l} \mathrm{Transfer}(o) = \\ \begin{cases} 0 & \text{default} \\ 1 & \text{explicitly enabled} \end{cases} \end{array} \right]$$

User Impact & Flow

User Experience

- Items sell out quietly
- No aftermarket chaos
- No bots
- No price manipulation

Why This Works

- Preserves trust
- Protects artists
- Prevents hoarding
- Keeps focus on the event

Scarcity in WeUP is **ontological**, not financialized.

Chapter 5 Closing Frame

WeUP pricing systems obey three invariants:

1. **Prices move for reasons users can feel**
2. **Scarcity reflects reality, not hype**
3. **No one profits from flipping culture**

This is how WeUP avoids the two failure modes of modern commerce:

- infinite cheapness
- infinite speculation

Instead, it produces **finite, meaningful exchange**.

Next Chapter (Natural Continuation)

6. Vendors, Artists & Venues

6.1 Vendor Onboarding & Identity

6.2 Artist-Led Microeconomies

6.3 Venue-Owned Cultural Capital

6.4 Collaborative Drops & Co-Creation

That chapter defines *who is allowed to sell, under what constraints, and how WeUP protects creators without becoming a gatekeeper*.

Below is a **fully rewritten, canonical Section 6** of the **WeUP Shop Bible**.

This version is **complete, internally consistent, system-accurate**, and written as a document that engineering, product, partnerships, and governance can all execute against.

This section **supersedes** prior drafts of Section 6 and is aligned with the unified WeUP architecture and cartography already defined .

6. Vendors, Artists & Venues

The WeUP Shop does not allow “anyone to sell anything.”

Every seller in WeUP is a **situated economic actor** whose legitimacy, scope, and revenue rights are derived from *events*, not platform-wide permissions.

This section defines:

- who is allowed to sell,
- under what conditions,
- how value flows,
- and how WeUP prevents events from collapsing into marketplaces.

The core principle is simple:

Commerce in WeUP is a function of contribution, not reach.

6.0 Seller Ontology (Shared Foundations)

All sellers in WeUP—vendors, artists, and venues—are modeled under a common abstraction:

Let a seller entity be:

[
s = (I_s, R_s, E_s, $\mathcal{C}_s$, $\mathcal{P}_s$)
]

Where:

- (I_s) = seller identity (pseudonymous, verifiable)
- (R_s) = seller role (vendor | artist | venue)
- (E_s) = set of events the seller is authorized to operate within
- ($\mathcal{C}_s$) = contractual constraints
- ($\mathcal{P}_s$) = payout graph node(s)

A seller **cannot exist independently of events**.

There is no global seller storefront, no permanent catalog, and no platform-wide visibility.

This is the first and most important constraint.

6.1 Vendor Systems

Definition

A **Vendor** is an event-scoped seller of goods or services whose value is primarily **functional** rather than expressive.

Examples:

- food and beverage providers
- apparel sellers
- local artisans
- on-site service providers

System Architecture

Vendor Identity Service

- Registers vendor entities with:
 - legal or pseudonymous identity
 - compliance metadata (health permits, licenses where applicable)
 - optional wallet bindings
- Identity is *not* social; there are no followers or feeds.

Event Authorization Layer

- Vendors must be explicitly authorized per event.
- Authorization defines:
 - sale window
 - allowed product categories
 - maximum inventory
 - payout terms

Commerce Runtime

- Vendor shops are instantiated **only during authorized event phases**.
- Inventory objects inherit event constraints automatically.

Business Logic

- Vendors cannot sell outside event time windows.
- Vendors cannot message users post-event unless explicitly permitted.
- Vendors do not retain customer lists.
- Vendors may participate in:
 - live shops
 - post-event residual fulfillment
- Vendors may **not** create recursive or lineage-bound artifacts by default.

User Impact

For attendees:

- Vendor offerings feel *situated*, not commercialized.
- No follow-up spam.
- No unrelated upsells.

For vendors:

- Clear scope and rules.
 - Guaranteed settlement windows.
 - Reputation is earned through fulfillment and reliability, not advertising.
-

6.2 Artist-Led Commerce Systems

Definition

An **Artist** is a seller whose value is **expressive, cultural, or narrative**, and whose economic agency extends beyond a single event.

Examples:

- musicians
- visual artists
- performers
- writers
- cultural producers

System Architecture

Artist Identity Layer

- Supports:
 - pseudonymous identities
 - wallet binding
 - role-based permissions
- Artists may have *cross-event continuity*.

Artist Micro-Shop Engine

- Artists can operate:
 - event-bound shops
 - delayed-release shops
 - post-event memory shops

- Inventory may include:
 - physical artifacts
 - digital artifacts
 - hybrid objects
 - ritual objects
 - memory objects

Rights & Royalty Contracts (Soroban)

- Encode:
 - revenue splits
 - residual rights
 - expiry
 - transferability rules
- Contracts are immutable once live.

Mathematical Revenue Model

Let artist revenue for event (E) be:

$$P_{\text{artist}}(E) = \alpha_E \cdot R_E + \sum_{i \in \mathcal{O}_E} \beta_i \cdot R_i$$

Where:

- (R_E) = event net revenue
- (α_E) = artist's event share
- (R_i) = revenue from artifact (i)
- (β_i) = artifact-specific royalty

Business Logic

- Artists control:
 - pricing curves
 - release timing
 - eligibility gates
- Artists may enable:
 - recursive access objects
 - lineage-based unlocks
- Artists are protected from:
 - resale speculation
 - unauthorized redistribution

User Impact

For attendees:

- Supporting an artist feels direct and meaningful.
- Purchases carry narrative weight.
- Ownership is contextual, not extractive.

For artists:

- Sustainable economics.
 - Long-tail memory revenue without infinite catalogs.
 - Creative control preserved.
-

6.3 Venue-Owned Cultural Capital

Definition

A **Venue** is not just infrastructure.

In WeUP, a venue is a **cultural amplifier** with economic participation rights.

Examples:

- clubs
- theaters
- galleries
- pop-up spaces
- municipally operated venues

System Architecture

Venue Identity Service

- Registers:
 - venue metadata
 - capacity constraints
 - location masking rules
 - payout wallets

Venue Residual Node

- Each event at a venue creates a **venue node** in the revenue graph.
- Venue nodes may receive:
 - base hosting fees
 - residual shop percentages

- memory artifact royalties

Compliance & Trust Layer

- Tracks:
 - safety compliance
 - ritual adherence
 - dispute history

Revenue Model

Venue payout:

$$[P_{\text{venue}} = \gamma \cdot R_{\text{event}} + \delta \cdot R_{\text{residual}}]$$

Where:

- (γ) = hosting coefficient
- (δ) = residual participation coefficient

Both are capped and time-bounded.

Business Logic

- Venues cannot impose arbitrary fees.
- Venue revenue must be declared before event launch.
- Venues may lose privileges for repeated violations.

User Impact

For attendees:

- Venues feel invested in the event's success.
- Cultural trust increases.

For venues:

- Revenue aligns with quality, not churn.
- Long-term participation encouraged.

6.4 Collaborative Drops & Co-Creation

Definition

A **Collaborative Drop** is an artifact created by **two or more seller entities** sharing authorship, meaning, and revenue.

Examples:

- artist × venue posters
- sponsor-funded ritual artifacts
- multi-artist collections

System Architecture

Collaboration Contracts

- Multi-sig approval required.
- Contract defines:
 - contributors
 - revenue splits
 - supply limits
 - eligibility logic

Artifact Lifecycle Manager

- Ensures:
 - no unilateral changes
 - no silent over-minting
 - deterministic settlement

Business Logic

- Collaboration artifacts:
 - are usually scarce
 - often ritual-gated
 - carry higher meaning density
- All collaborators must approve activation.

User Impact

For attendees:

- Clear provenance.
- Higher trust in authenticity.
- Objects feel “earned,” not mass-produced.

6.5 Seller Reputation & Enforcement

Reputation Model

Seller reputation is:

- event-scoped
- multi-dimensional
- decaying over time

Metrics include:

- fulfillment reliability
- dispute resolution
- ritual compliance
- contribution quality

No public scores.

No gamification.

Enforcement Logic

- Violations trigger:
 - scoped suspensions
 - reduced privileges
 - revenue holds
- Enforcement is:
 - auditable
 - appealable
 - human-reviewed

Section 6 Closing Frame

Vendors, artists, and venues are not “users” of WeUP.

They are **participants in a coordinated cultural economy**.

By enforcing:

- event-bounded authority,

- transparent revenue graphs,
- non-extractive commerce rules,

WeUP ensures that selling never overwhelms gathering.

Commerce becomes **supportive**, not dominant.

Economic value becomes **earned**, not harvested.

Next Section

7. Sponsor & Brand Activation

(How capital participates without colonizing culture)

7. Sponsor & Brand Activation

7.1 Non-Intrusive Sponsorship

7.2 Ritual-Aligned Brand Goods

7.3 Sponsor Residual Participation

Below is the **fully written, canonical Section 7** of the **WeUP Shop Bible**, expanded to include **social-gravity-based sponsorship, sponsored user-created events, sponsor reward mechanics, a Sponsor Portal, and deep blockchain integration.**

This section is written to be directly actionable by **engineering, partnerships, product, and governance**—not as marketing language.

7. Sponsor & Brand Activation

In WeUP, sponsors do not buy attention.

They **underwrite meaning**.

Sponsorship is treated as a **conditional capital flow** that activates only when cultural legitimacy is proven. No banners. No interruptions. No algorithmic coercion.

Sponsors participate in WeUP as **patrons bound by rules**, not advertisers granted exceptions.

7.0 Sponsor Ontology & Structural Role

A sponsor in WeUP is defined as:

$$b = (l_b, \mathcal{E}_b, \mathcal{S}_b, \mathcal{R}_b, \mathcal{W}_b)$$

Where:

- (l_b) = sponsor identity (brand, foundation, or organization)
- $(\mathcal{E}_b)$ = eligible event types
- $(\mathcal{S}_b)$ = sponsorship scope and constraints
- $(\mathcal{R}_b)$ = reward commitments (goods, subsidies, funding)
- $(\mathcal{W}_b)$ = blockchain settlement wallets

Sponsors **cannot self-insert** into events.

They may only activate through **explicit contracts** triggered by **cultural conditions**.

7.1 Non-Intrusive Sponsorship

Purpose

Enable sponsors to fund events and commerce **without hijacking user attention or behavior**.

System Architecture

Sponsor Identity Service

- Registers sponsors with:
 - legal entity or DAO identity
 - ethical constraints (e.g., no alcohol at youth events)
 - approved product categories
- Sponsors are vetted before activation.

Sponsor Portal (Backend + UI)

- Sponsors configure:
 - sponsorship offers
 - eligibility conditions
 - maximum exposure limits
- Sponsors cannot:
 - message users
 - collect personal data
 - inject UI elements outside allowed surfaces

Event Sponsorship Contract (Soroban)

- Defines:
 - funding amount
 - activation conditions
 - reward delivery rules
 - residual participation (if any)
- Funds are escrowed until conditions are met.

Blockchain Integration

- Sponsor funds are locked in a **Soroban escrow contract**.
- Contract includes:
 - `activate()` callable only when conditions are verified.
 - `refund()` or `redirect()` paths if activation fails.
- Settlement occurs via **Stellar** once activation is confirmed.

User Impact

- No ads.
- No brand takeovers.
- Sponsor presence is contextual and subtle:
 - “This ritual is supported by...”
 - “This item is made possible by...”

Sponsors feel like **patrons**, not intrusions.

7.2 Ritual-Aligned Brand Goods

Purpose

Allow sponsors to offer products **only when collective action succeeds**.

This aligns capital with behavior—**not clicks**.

System Architecture

Ritual–Sponsor Binding

- Sponsors commit goods or funds to a ritual outcome.
- Ritual Engine emits:
 - success/failure state
 - participation density
- Sponsor Contract listens for this event.

Sponsored Inventory Engine

- Sponsored goods are:
 - pre-registered
 - supply-capped
 - non-transferable by default
- Items unlock only on ritual success.

Reward Distribution Flow

- On success:
 - sponsored goods appear seamlessly in the event shop
 - prices may be reduced or zeroed
- On failure:
 - goods never appear
 - funds are redirected per contract (e.g., community fund).

Mathematical Trigger

Let ritual completion be $(C_R(t))$:

```
[  
\text{SponsorActivation} =  
\begin{cases}  
1 & \text{if } C_R(t) \geq \theta \\  
0 & \text{otherwise} \\  
\end{cases}  
]
```

User Impact

- Users feel rewarded for participation, not manipulation.
- Sponsored goods feel *earned*, not promotional.
- No opt-ins, no forms, no data exchange.

The sponsor's brand equity increases through **alignment**, not visibility.

7.3 Sponsor Residual Participation

Purpose

Allow sponsors to share in post-event economic success **without owning culture**.

System Architecture

Residual Sponsorship Token

- Sponsors may receive a **non-transferable residual token** tied to a specific event.
- Token entitles sponsor to a capped share of residual shop revenue.

Revenue Graph Integration

- Sponsor node is added to the event payout graph.
- Sponsor share:
 - capped
 - time-bounded
 - subordinate to creators and venues

Revenue Formula

$$[P_{\text{sponsor}} = \min(\eta \cdot R_{\text{residual}}; P_{\text{max}})]$$

Where:

- (η) = sponsor residual coefficient
- (P_{max}) = maximum allowed sponsor return

Business Logic

- Sponsors cannot extract indefinite value.
- Residuals expire automatically.
- Sponsors may redirect residuals to:
 - future events
 - grants
 - community treasuries

User Impact

- Purchases transparently support both culture and patronage.
 - No hidden profit siphoning.
 - Trust remains intact.
-

7.4 Social-Gravity-Triggered Sponsorship for User-Created Events

Purpose

Allow **user-created events** to attract sponsors **only when they demonstrate real cultural pull**.

Social Gravity Model

Each event (E) has a **Social Gravity Score** (G(E)):

$$[G(E) = w_1 A + w_2 L + w_3 P + w_4 R]$$

Where:

- (A) = confirmed attendance density
- (L) = invite lineage depth
- (P) = ritual participation rate
- (R) = creator reputation

Sponsor Matching Engine

- Sponsors define:
 - minimum gravity threshold
 - event type preferences
 - geographic constraints
- When $G(E) \geq G_{\min}$:
 - event becomes *sponsor-eligible*
 - sponsors may offer conditional funding

Blockchain Enforcement

- Sponsor offers are **on-chain commitments**, not promises.
- Funds are escrowed until:
 - event launches
 - minimum attendance is met
- No sponsor can withdraw after activation.

User Impact

- Grassroots events gain access to funding organically.

- Creators are rewarded for community building.
 - Sponsors support real momentum—not inflated metrics.
-

7.5 Sponsor Reward System (User-Facing)

Purpose

Allow users to receive sponsored rewards **without friction or coercion**.

System Architecture

Sponsor Reward Objects

- Modeled as:
 - inventory items
 - discount modifiers
 - access unlocks
- Delivered automatically based on eligibility.

Eligibility Engine Integration

- Rewards may be gated by:
 - attendance
 - ritual participation
 - tier or lineage
- No additional actions required.

Shop Integration

- Sponsored rewards appear:
 - inline with normal shop items
 - visually distinct but subtle
- No pop-ups or call-to-actions.

User Impact

- Rewards feel native.
 - No brand fatigue.
 - Participation feels appreciated, not tracked.
-

7.6 Sponsor Portal & Shop Integration

Sponsor Portal Capabilities

Sponsors can:

- define sponsorship offers
- set gravity thresholds
- allocate funds across multiple events
- view anonymized impact analytics
- manage escrowed funds

Sponsors cannot:

- modify event content
- message users
- override ritual logic
- access personal data

Shop Integration

- Sponsored items obey **all shop rules**:
 - eligibility logic
 - scarcity constraints
 - pricing systems
- The shop remains consistent regardless of sponsorship.

Sponsors adapt to WeUP—not the other way around.

7.7 Structural Blockchain Integration Summary

Sponsors are integrated via:

- **Soroban Contracts**
 - escrow
 - activation logic
 - residual participation
- **Stellar Settlement**
 - fast, transparent payouts
 - multi-party revenue distribution
- **On-Chain Auditability**
 - all sponsor commitments are verifiable

- no silent changes
- no off-book deals

This ensures **trust without reliance on platform goodwill**.

Section 7 Closing Frame

WeUP sponsorship succeeds because it obeys three invariants:

1. **Sponsors earn presence through alignment, not money alone**
2. **Users receive value without surrendering attention or data**
3. **Capital is bound by culture, not the reverse**

Sponsors become **supporting actors**, not directors.

Next Section

8. Revenue Distribution & Contract Graphs

(How money moves deterministically, transparently, and fairly across all participants)

Below is the **fully written, canonical Section 8** of the **WeUP Shop Bible**.

This section formalizes **how money moves through WeUP**—upstream and downstream—across **creators, invite lineages, tiers, sponsors, venues, and the platform itself**, without collapsing into extraction or pyramid dynamics.

This is the **economic spine** of WeUP.

8. Revenue Distribution & Contracts

Revenue in WeUP is not pooled and redistributed later.

It is **routed deterministically at the moment of settlement**.

Every dollar (or tokenized equivalent) entering WeUP is immediately mapped onto a **directed contract graph** that defines:

- who is paid,
- how much,
- for how long,

- and under what conditions.

There is no opaque treasury.

There is no discretionary redistribution.

Only graphs.

8.0 Revenue Graph Primitives

All WeUP revenue flows conform to a common structure.

Let a revenue event be (R) , generated by:

- ticket sales,
- shop purchases,
- residual shop activity,
- sponsor funding.

Each revenue event instantiates a **Revenue Graph**:

[
 $\mathcal{G}_R = (V, E, W, T)$
]

Where:

- (V) = payout nodes (artists, vendors, venue, lineage, sponsor, platform)
- (E) = directed edges
- (W) = edge weights (percentages)
- (T) = temporal constraints (activation + expiry)

Invariant:

[
 $\sum_{e \in E} W_e = 1$
]

No edge may be added or modified after activation.

8.1 Event Revenue Graphs

Purpose

Define how **primary event revenue** (tickets + live shop sales) is distributed across all stakeholders.

Graph Structure

A typical event revenue graph includes nodes for:

- Primary creators (artists, hosts)
- Venue
- Vendors
- Sponsor (if applicable)
- Lineage pools
- WeUP platform (capped)

Edges encode **pre-agreed revenue shares**.

Example structure (conceptual):

- 55% → Artists / Hosts
- 15% → Venue
- 10% → Vendors (proportional to sales)
- 10% → Lineage Pool
- 5% → Sponsor residual (if enabled)
- 5% → WeUP platform

Tier-Aware Distribution

The **three-tier invite system** influences *who* can participate in revenue, not *how much exists*.

- **Tier 1 (Inner):**
 - Full eligibility for lineage payouts
 - Eligible for governance and residual extensions
- **Tier 2 (Mid):**
 - Limited lineage payouts
 - Time-bounded participation
- **Tier 3 (Outer):**
 - No direct revenue participation
 - Participation affects social gravity only

This prevents dilution while still rewarding cultural builders.

User Impact

- Creators know their payout before the event launches.
 - Venues and vendors trust settlement because it is automatic.
 - Attendees indirectly support multiple layers of culture with each purchase.
-

8.2 Residual Ownership Models

Purpose

Enable **long-tail revenue** without infinite extraction.

Residuals exist only where meaning persists.

Residual Sources

Residual revenue may originate from:

- post-event shops
- memory artifacts
- delayed releases
- archival access

Each residual source spawns its **own subgraph**, derived from the original event graph.

Residual Ownership Tokens

For each event (E), WeUP may mint **Residual Ownership Tokens (ROT)**s:

$$\begin{bmatrix} \text{ROT}_E = (V_r, W_r, \tau) \end{bmatrix}$$

Where:

- (V_r) = residual-eligible nodes
- (W_r) = residual weights
- (τ) = expiry timestamp

Key constraints:

- Non-transferable by default
- Expire automatically
- Cannot exceed capped percentages

Downstream Creator Protection

- Artists always retain the largest residual share.
- Venues and sponsors are capped.
- Platform share may decay over time.

This ensures:

- Creators benefit from sustained relevance
- No entity profits indefinitely from a past event

User Impact

- Buying a memory object supports creators long-term.
 - Residuals feel fair, not predatory.
 - Old events eventually rest.
-

8.3 Lineage-Based Payouts

Purpose

Reward **cultural propagation** without creating financial pyramids.

Lineage payouts are **acknowledgments**, not income strategies.

Invite Lineage Graph

Invites form a **Directed Acyclic Graph (DAG)**:

- Nodes = identities
- Edges = invite relationships
- Depth = distance from event root

Only **Tier 1 and Tier 2** participants may earn lineage payouts.

Lineage Pool Formation

A fixed percentage (β) of event revenue is allocated to the **Lineage Pool**.

$$\begin{aligned} [\\ R_{\text{lineage}} &= \beta \cdot R_{\text{event}} \\] \end{aligned}$$

Distribution Function

Payout to inviter (i):

$$P_i = R_{\{\text{lineage}\}} \cdot g(d_i)$$

Where:

- (d_i) = lineage depth
- $(g(d))$ = decay function (e.g., exponential or harmonic)

Constraints:

- Maximum depth cutoff
- Hard cap on total lineage allocation
- No recursive compounding

Sponsor Interaction

Sponsors may:

- contribute additional funds to the lineage pool
- **not** receive lineage payouts themselves

This preserves lineage as a **community reward**, not a marketing channel.

User Impact

- Inviting meaningful participants is rewarded.
- Spam invites yield nothing.
- Lineage reinforces trust, not hustle.

8.4 Transparent Settlement

Purpose

Ensure **trustless, verifiable, real-time settlement** across a distributed network.

Settlement Architecture

Soroban Contracts

- Encode revenue graphs
- Enforce weights, caps, and expiries
- Validate all settlement calls

Stellar Network

- Executes payouts:
 - fast
 - low-fee
 - multi-recipient
- Supports atomic distribution

Settlement Service

- Triggers payouts on:
 - purchase events
 - shop closures
 - residual intervals

Upstream & Downstream Visibility

Upstream (Creators, Venues, Sponsors):

- See:
 - inflows
 - payout schedules
 - residual balances
- Cannot modify graphs post-activation

Downstream (Users):

- See:
 - percentage breakdowns
 - cultural impact summaries
- Never see private wallets or identities

Dispute & Hold Logic

- Disputes can:
 - pause future settlements
 - never reverse completed payouts
- All actions are logged and auditable.

User Impact

- Creators get paid quickly and predictably.
 - Sponsors trust their capital is used correctly.
 - Users trust the platform because money obeys code.
-

8.5 Integrated WeUP Revenue Structures (Summary)

WeUP revenue originates from multiple coordinated mechanisms:

- **Primary Event Revenue**
 - Tickets
 - Live shops
- **Post-Event Residual Revenue**
 - Memory objects
 - Limited archival access
- **Sponsor Capital**
 - Event underwriting
 - Ritual-aligned rewards
 - Conditional residual participation
- **Platform Revenue**
 - Capped service fees
 - Time-decaying participation

Each mechanism:

- has explicit bounds,
 - respects tiered access,
 - and routes value through transparent graphs.
-

Section 8 Closing Frame

WeUP does not ask participants to **trust the platform**.

It asks them to **verify the math**.

By combining:

- revenue graphs,
- lineage-aware distribution,
- tier-bounded participation,
- sponsor capital with constraints,

WeUP creates a distributed economy where:

Money follows meaning,
meaning follows presence,
and presence cannot be faked.

Next Section

9. Memory, Afterlife & Continuity

(How events persist without becoming feeds, and how culture is allowed to rest)

Below is the **canonical Section 9** of the **WeUP Shop Bible**, rewritten with **greater philosophical depth, temporal prosody, and sociological grounding**, while remaining **technically and scientifically honest**.

This section answers a difficult question most platforms avoid:

What should happen *after* something meaningful ends?

9. Memory, Afterlife & Continuity

Most digital systems fear endings.

They convert moments into feeds, events into content, and memories into endlessly resurfaced artifacts—flattened, repeated, stripped of context. This is not how humans remember. This is how systems extract.

WeUP takes a different stance:

An event deserves an afterlife, not an echo chamber.

Memory in WeUP is not infinite persistence.

It is **structured decay, selective resurfacing, and intentional continuity**.

This section defines how events live on—and *when they are allowed to rest*.

9.1 Post-Event Access

Philosophical Frame

Immediately after an event, people are not ready to consume it again.

Neuroscience supports this: memory consolidation requires **time**, not instant replay.

Platforms that push content immediately after an experience:

- disrupt emotional processing,
- cheapen significance,
- replace reflection with capture.

WeUP delays.

Timeline Reality

T₀ — Event Ends

- Live shops close.
- No new purchases.
- No recap feeds.

T₀ + 24–72 hours

- Post-event access window opens.
- Attendees receive quiet notifications.
- Memory artifacts become *available*, not *pushed*.

System Architecture

Post-Event Portal

- Gated by:
 - attendance proof
 - tier eligibility
- Surfaces:
 - curated artifacts
 - artist reflections
 - limited memory objects

Access Constraints

- Finite window (e.g., 14–90 days).
- No infinite rewatching by default.
- No algorithmic resurfacing.

Pain Points Addressed

- **Pain:** “I feel pressure to capture everything.”
- **Resolution:** The system captures selectively, so the human doesn’t have to.
- **Pain:** “I forget meaningful moments.”
- **Resolution:** Memory arrives after emotional processing, improving recall quality.

User Experience Outcome

Memory feels like a gift, not a chore.

Access feels earned, not exploited.

9.2 Dormant Items

Philosophical Frame

Some things should not be available yet.

Human meaning often unfolds **retroactively**—we understand moments only after living with them. Dormant items acknowledge this temporal truth.

Timeline Reality

Dormant items follow **activation arcs**:

- **Short Dormancy:** days or weeks (reflection artifacts)
- **Medium Dormancy:** months (anniversary unlocks)
- **Long Dormancy:** years (cultural time capsules)

System Architecture

Dormant Artifact Contracts

- Define:
 - activation timestamp
 - activation conditions (e.g., return attendance)
- Lock content or physical redemption until conditions are met.

Monitoring Service

- Checks conditions periodically.
- Triggers unlock events.
- Notifies users quietly.

Pain Points Addressed

- **Pain:** “Everything feels disposable.”
- **Resolution:** Delayed activation increases perceived and actual value.
- **Pain:** “There’s no reason to revisit past events.”
- **Resolution:** Dormant items create meaningful future touchpoints.

User Experience Outcome

Objects mature alongside the person.
Meaning accrues instead of evaporating.

9.3 Cultural Echoes

Philosophical Frame

Culture does not repeat itself; it **resonates**.

Cultural echoes are not copies of past events—they are *references* that inform future gatherings without dominating them.

Timeline Reality

Cultural echoes operate across **event sequences**:

- Event A plants an artifact.
- Event B recognizes it.
- Event C transforms it.

Echoes are sparse by design.

System Architecture

Echo Linkage

- Memory objects may carry:
 - symbolic identifiers
 - eligibility flags for future events
- Future events may choose to:
 - honor the echo
 - ignore it entirely

Constraint Logic

- Echoes:
 - cannot stack infinitely
 - cannot be traded as access tokens
 - expire after use or time

Pain Points Addressed

- **Pain:** “Communities lose continuity.”
- **Resolution:** Echoes allow continuity without repetition.
- **Pain:** “Past events overshadow new ones.”
- **Resolution:** Echoes are optional and attenuated.

User Experience Outcome

Returning participants feel recognized.

New participants are not excluded.

Culture remembers without clinging.

9.4 Long-Tail Economic Memory

Philosophical Frame

There is a difference between *archiving* and *monetizing memory*.

Most platforms monetize indefinitely, turning nostalgia into a subscription. This creates resentment, fatigue, and cultural stagnation.

WeUP imposes an ending.

Timeline Reality

Residual Phases

- **Phase 1 (Immediate Residual):** weeks to months
Memory objects, limited editions.
- **Phase 2 (Archival Residual):** months to years
Rare artifacts, higher pricing.
- **Phase 3 (Closure):** permanent shutdown
Shop closes. Remaining artifacts are retired or donated.

System Architecture

Long-Tail Shop

- Operates under:
 - capped supply
 - time-based price increase
 - automatic sunset

Residual Contracts

- Ensure:
 - payouts continue during the tail
 - no extension beyond expiry
 - no platform override

Pain Points Addressed

- **Pain:** “Everything is always available, so nothing matters.”
- **Resolution:** Scarcity through time, not hype.
- **Pain:** “Creators are exploited long after events.”
- **Resolution:** Residuals expire. Extraction stops.

User Experience Outcome

Latecomers pay a premium *by choice*.

Original participants retain primacy.

Events are allowed to end with dignity.

Section 9 Closing Frame

WeUP treats memory as **a living process**, not a database.

- Some memories arrive later.
- Some remain dormant.
- Some echo forward.
- Some fade—and should.

By respecting:

- neurological consolidation,
- sociological meaning-making,
- cultural fatigue limits,

WeUP avoids the central failure of digital culture:

The refusal to let anything end.

An event that never ends
was never really lived.

Next Section

10. Ethical Constraints & Anti-Extraction Rules

(How WeUP prevents memory, commerce, and culture from becoming exploitative systems)

Below is the **canonical Section 10** of the **WeUP Shop Bible**.

This section is deliberately slower, firmer, and more principled than the others—because ethics are not features. They are **load-bearing constraints**.

This chapter exists to prevent WeUP from becoming what most successful platforms eventually become.

10. Ethical Constraints & Anti-Extraction Rules

Every economic system trends toward extraction unless actively constrained.

This is not ideology; it is observable behavior across markets, platforms, and institutions. When incentives reward attention capture, resale, or surveillance, systems will eventually optimize for those outcomes—even if they begin with good intentions.

WeUP assumes this risk **from the beginning** and encodes counter-pressures directly into its architecture.

Ethics in WeUP are not enforced by policy documents alone.
They are enforced by **what the system refuses to allow**.

10.1 No Infinite Feeds

Philosophical Grounding

Infinite feeds are not neutral interfaces.

They are **behavior-shaping mechanisms** designed to suppress stopping signals in the human brain.

Cognitive science is clear on this point:

Humans rely on *boundaries* to regulate attention. Remove boundaries, and attention degrades into compulsion.

WeUP rejects the premise that culture should compete for uninterrupted attention.

Structural Constraint

There is **no global feed** in WeUP.

No endless scroll.

No algorithmic resurfacing of past events.

No “recommended for you” commerce stream.

System Architecture

- All shops are:
 - event-scoped
 - time-bounded
 - eligibility-limited
- Content surfaces appear only:
 - within explicit user intent flows
 - during defined temporal windows
- When a shop closes, it **ceases to exist in the UI**.

There is no archival browsing mode that resembles a feed.

Pain Points Addressed

- **Pain:** “I feel pulled to check apps endlessly.”
- **Resolution:** The system ends sessions for you.
- **Pain:** “Events blur together.”
- **Resolution:** Each event has a clear beginning and end.

Ethical Outcome

WeUP optimizes for **presence**, not retention.

The system respects the human need to disengage.

10.2 No Speculative Markets

Philosophical Grounding

Speculation transforms meaning into price signals.

Once an object's primary value becomes resale potential, its cultural value collapses.

This has been observed repeatedly:

- art markets
- ticket scalping
- digital collectibles
- limited edition merchandise

Speculation rewards hoarding, not participation.

Structural Constraint

By default:

- objects are non-transferable
- resale is disallowed
- secondary marketplaces are unsupported

Transferability must be **explicitly enabled**, narrowly scoped, and justified.

System Architecture

- Artifact contracts include:
 - transfer flags (off by default)
 - usage constraints
 - expiration rules
- No open marketplace exists inside WeUP.
- No API supports external resale indexing.

Even when transfers are allowed:

- they are capped
- they are slow
- they are auditable

Pain Points Addressed

- **Pain:** "Bots and scalpers ruin access."
- **Resolution:** There is nothing to flip.

- **Pain:** “People buy things they don’t care about.”
- **Resolution:** Profit motive is structurally minimized.

Ethical Outcome

Objects are acquired for **meaning**, not leverage.
Scarcity protects culture, not capital.

10.3 Consent-Bound Commerce

Philosophical Grounding

Consent is not a checkbox.
It is an **ongoing state**.

Most platforms treat consent as a one-time transaction that permanently licenses surveillance.
This is not aligned with human expectations or ethical data stewardship.

WeUP treats consent as:

- granular
- revocable
- context-dependent

Structural Constraint

No actor in WeUP—vendor, artist, sponsor, or platform—receives personal data by default.

Data flows are **opt-in, scoped, and reversible**.

System Architecture

Consent Ledger

- Records:
 - what data is shared
 - with whom
 - for how long
- Anchored cryptographically for auditability.
- Revocation halts future data flow immediately.

Data Minimization

- Vendors receive:
 - aggregate sales data
 - fulfillment metrics
- Sponsors receive:
 - anonymized impact metrics
- No party receives:
 - emails
 - behavioral profiles
 - cross-event tracking

Pain Points Addressed

- **Pain:** “I don’t know who has my data.”
- **Resolution:** Consent states are visible and revocable.
- **Pain:** “I feel watched.”
- **Resolution:** Surveillance is structurally disincentivized.

Ethical Outcome

Commerce does not require surveillance.
Participation does not cost privacy.

10.4 Cultural Protection Policies

Philosophical Grounding

Culture is not neutral.
It carries history, power dynamics, and vulnerability.

When systems ignore this, they enable:

- appropriation
- commodification of sacred practices
- harm through ignorance rather than malice

WeUP treats cultural protection as a **first-class system concern**, not a PR afterthought.

Structural Constraint

Certain cultural expressions:

- cannot be sold

- cannot be remixed freely
- require contextual consent

Not everything meaningful should be monetized.

System Architecture

Cultural Review Layer

- Human-in-the-loop review for:
 - ritual objects
 - symbolic artifacts
 - culturally sensitive practices
- Reviews are:
 - scoped
 - appealable
 - transparent in reasoning

Algorithmic Safeguards

- Pattern detection flags:
 - exploitative symbolism
 - misaligned usage contexts
- Flags pause launches—not punish users.

Pain Points Addressed

- **Pain:** “My culture is used without respect.”
- **Resolution:** Explicit review and consent pathways.
- **Pain:** “Platforms only act after harm.”
- **Resolution:** Preventative constraints.

Ethical Outcome

WeUP protects culture by **slowing commerce**, not accelerating it.

Respect is enforced structurally, not rhetorically.

Section 10 Closing Frame

WeUP does not claim moral superiority.

It simply acknowledges a truth most systems ignore:

If you do not design against extraction, extraction will design itself in.

By eliminating:

- infinite feeds,
- speculative incentives,
- coercive data practices,
- and cultural exploitation,

WeUP creates space for something rare:

A commercial system that **stops where it should**.

Not everything needs to scale.

Not everything should persist.

Not everything must be monetized.

Next Section

11. Future Expansion Layers

(How WeUP grows without violating everything it just promised)

Below is the **canonical Section 11** of the **WeUP Shop Bible**.

This chapter is intentionally forward-looking but disciplined. Everything described here is an **extension**, not a mutation, of the constraints already established. Growth in WeUP is not additive; it is **compositional**.

Nothing in this section violates Sections 1–10. If it did, it would not be allowed to exist.

11. Future Expansion Layers

Expansion is where most systems betray themselves.

They grow horizontally—more users, more content, more surfaces—until the original values are diluted beyond recognition. WeUP grows **vertically**, adding depth, not sprawl.

Future layers are activated only when:

- cultural density exists,
- governance structures are ready,
- and extraction risks are contained.

This section outlines the layers that may emerge *only when the system has earned them*.

11.1 Ritual Economies

Philosophical Frame

A ritual economy is not a market that happens to include rituals.
It is an economy whose **unit of value is participation over time**.

Historically, ritual economies exist wherever:

- meaning is shared repeatedly,
- participation compounds trust,
- and outcomes matter collectively.

WeUP formalizes this without mysticism or abstraction.

Structural Definition

A **Ritual Economy** is a persistent economic layer bound to a recurring ritual sequence:

[
 $\mathcal{R} = (E_1, E_2, \dots, E_n)$
]

Where value accrues only through **continued participation**, not one-off attendance.

System Architecture

- **Ritual Treasury**
 - A pooled fund created from:
 - ritual-aligned purchases
 - sponsor contributions
 - voluntary participant allocations
 - Funds are locked and governed collectively.
- **Participation Ledger**
 - Tracks ritual attendance and completion states.
 - Does not expose identities publicly.
 - Used only to determine eligibility, not rank.
- **Governance Thresholds**
 - Decisions (e.g., how funds are used) require quorum.
 - Quorum is weighted by *duration of participation*, not wealth.

Timeline Reality

Ritual economies emerge over **months or years**, not events.
They are slow by necessity.

Pain Points Addressed

- **Pain:** “Communities dissolve after events.”
- **Resolution:** Shared economic continuity.
- **Pain:** “Only organizers benefit long-term.”
- **Resolution:** Value accrues to sustained participants.

Cultural Outcome

Ritual economies reward *showing up again*, not showing off once.

11.2 DAO-Curated Shops

Philosophical Frame

Curation is a form of power.

If left centralized, it becomes taste-making tyranny.

If left unbounded, it becomes chaos.

DAO-curated shops exist to **distribute curatorial authority without dissolving responsibility**.

Structural Definition

A **DAO-Curated Shop** is a shop whose inventory, pricing logic, and activation timing are governed by a bounded participant collective.

System Architecture

- **Governance Tokens**
 - Earned through:
 - event participation
 - ritual completion
 - cultural contribution
 - Non-transferable.
 - Expire if unused.
- **Proposal System**

- Participants propose:
 - new artifacts
 - collaborations
 - pricing changes
- Proposals include:
 - scope
 - duration
 - economic impact
- **Execution Contracts**
 - Approved proposals are instantiated as immutable shop contracts.
 - No admin override once live.

Constraints

- No proposal can:
 - introduce infinite availability
 - enable speculative resale
 - override cultural protection policies
- Minority vetoes exist for culturally sensitive decisions.

Timeline Reality

DAO-curated shops appear only after:

- a stable ritual economy exists,
- participation density is high,
- governance fatigue risks are minimal.

Pain Points Addressed

- **Pain:** “Platforms decide taste.”
- **Resolution:** Taste is governed, not owned.
- **Pain:** “Voting systems are exhausting.”
- **Resolution:** Participation is optional and scoped.

Cultural Outcome

Curation becomes a shared responsibility, not an invisible algorithm.

11.3 AI-Assisted Curation

Philosophical Frame

AI should not decide what matters.
It can, however, **notice patterns humans miss**.

WeUP uses AI as an *assistant*, never an arbiter.

Structural Role

AI operates as a **suggestion engine**, not a decision-maker.

It may propose:

- artifact groupings
- pricing curve adjustments
- ritual timing optimizations
- sponsor alignment opportunities

It may never:

- activate commerce
- approve content
- override human governance

System Architecture

- **Pattern Analysis Models**
 - Analyze:
 - participation density
 - ritual success rates
 - artifact engagement
 - Operate on anonymized, aggregate data only.
- **Explainability Layer**
 - Every suggestion includes:
 - reason codes
 - confidence bounds
 - ethical impact notes
- **Human Review Loop**
 - Curators accept, modify, or reject suggestions.
 - Rejections feed back into model tuning.

Timeline Reality

AI assistance is introduced gradually, after baseline behaviors stabilize.

Pain Points Addressed

- **Pain:** “Algorithms manipulate behavior.”
- **Resolution:** AI cannot act, only advise.
- **Pain:** “Human curation doesn’t scale.”
- **Resolution:** AI reduces cognitive load, not agency.

Cultural Outcome

AI amplifies attentiveness, not extraction.

11.4 Cross-Event Cultural Markets

Philosophical Frame

Most platforms flatten geography and context.
WeUP treats locality as **a source of meaning**, not friction.

Cross-event markets are **bridges**, not highways.

Structural Definition

A **Cross-Event Cultural Market** links two or more events through a shared artifact, ritual, or narrative thread.

These markets are:

- sparse
- intentional
- time-limited

System Architecture

- **Inter-Event Contracts**
 - Require:
 - consent from all event hosts
 - predefined revenue graphs
 - Define:
 - artifact scope
 - cultural constraints
 - sunset conditions
- **Reciprocity Logic**
 - Revenue is distributed proportionally across contributing events.
 - No event may dominate the outcome.

- **Geographic Sensitivity**
 - Certain artifacts may be location-bound.
 - Physical movement may be required for activation.

Timeline Reality

Cross-event markets typically emerge:

- after multiple successful events,
- when cultural alignment is evident,
- not as launch features.

Pain Points Addressed

- **Pain:** “Expansion erases local identity.”
- **Resolution:** Locality remains primary.
- **Pain:** “Networks feel generic.”
- **Resolution:** Connections are meaningful and rare.

Cultural Outcome

Culture travels without becoming diluted.

Section 11 Closing Frame

The future of WeUP is not scale for its own sake.

It is **earned complexity**.

Each expansion layer:

- deepens participation,
- increases responsibility,
- and raises the cost of misuse.

Nothing here exists to increase engagement metrics.
Everything exists to protect meaning under growth.

WeUP does not ask:
“How big can this become?”

It asks:
“How deep can this remain?”

End of the WeUP Shop Bible (Core Sections)

From here, future documents may branch into:

- governance charters,
- legal mappings,
- technical implementation specs,
- or regional adaptations.

But the philosophical, economic, and ethical foundation is now complete.

This system knows **what it will never become**—and that is its greatest strength.
