

Concierge — here's the **3-tier invite-only / trust-routed creator system** for WeUP, with the **math + operational methods** wired to *how creators publish, promote, sell, and get paid* (without turning WeUP into an affiliate-clout casino).

0) First principles (so the math doesn't drift into "social app nonsense")

WeUP explicitly wants **lineage over follower counts** and **presence over engagement**.

So: **tiers are visibility + permission layers**, not "status classes."

And **trust is a private routing field** used to decide things like "can this person publish events here / sell through Shop here?"

1) The 3 tiers (and what creators can actually do in each)

From the Identity Bible, the clean default stack is:

Tier A — Public

- Sees: teasers / broad area summaries (no exact address).
- Can do (creator-wise): submit flyers for parsing, request invites, share *teasers* without leaking ops details.

Tier B — Invited

- Sees: more precise event details + RSVP/purchase flows.
- Can do: hold passes/tickets; apply for some crew calls; **start operating as a real promoter node** (referrals, attribution, payouts).

Tier C — Vouched

- Sees: exact location + entry instructions; can see restricted/ops info when relevant.
- Can do: access higher-trust events, staff sensitive roles, post certain calls, join trusted circles.

This is where WeUP safely allows "creator circles" and deep event operations.

Default tier capabilities (from the Events spec draft) include: confirmed/deep reveal gating, after-hours reveal, and **limited invite issuance** for Tier 2/3.

2) Trust + vouching mathematics (the engine that upgrades creators safely)

2.1 Vouch graph model

We model vouching as a directed weighted graph: users are nodes, vouches are edges.

A vouch from (i to j) has weight ($w_{ij} \in [0, 1]$) and timestamp (t_{ij}). Its **decayed contribution** at time (t) is:

$$\begin{aligned} & [\\ & \tilde{w}_{ij}(t) = w_{ij} \cdot e^{-\lambda(t - t_{ij})} \\ &] \end{aligned}$$

The target's trust score (scoped to an event/cell) is:

$$\begin{aligned} & [\\ & T_j(t) = \min\left(T_{\max}, \sum_{i \in \text{In}(j)} \tilde{w}_{ij}(t)\right) \\ &] \end{aligned}$$

Role vouch explicitly exists for creators/vendors ("legit as a vendor/creator").

2.2 Anti-gaming constraints (so "trust" can't be bought or spammed)

Minimum rules in the Events spec include: issuer rate limits, weight caps, diversity requirements, reciprocal suppression, spike checks, and presence requirements. This is the part that prevents "pay-for-vouch markets."

2.3 Tier upgrade gates (actual thresholds)

The Tier ladder is explicitly defined like this in the Events spec: Tier 2 and Tier 3 require trust thresholds + diversity, and Tier 3 may require presence receipts.

Operationally:

- **Tier 2** if ($T_u(t) \geq \theta_2$) **and** diversity rule satisfied
- **Tier 3** if ($T_u(t) \geq \theta_3$) **and** diversity rule satisfied **and** optional presence rule satisfied (recent check-in receipt)

Also: reveal sets must be monotone (Tier 3 can't see less than Tier 2).

3) Invite system mechanics (how creators actually bring people in)

3.1 Invite object (fields)

The Ticketing TRD defines the Invite object fields:

InviteId, EventId, TierGranted, IssuerId, ExpirationTime, UsageLimit, Shareable, Revocable.

The PRD additionally requires invites encode issuer/recipient/tier/expiry and be revocable; and bans open signups + viral invite loops.

3.2 Invite flow (state transitions)

1. Invite issued → 2) user claims → 3) tier state updates → 4) ticket types filter by tier.

3.3 “Invite issuance ability” is bounded

Tier capability table marks invite issuance as **limited + logged** (Tier 2/3).

So the platform can support creator growth without spawning spam economies.

4) Creator permissions are computed like a policy decision (not vibes)

WeUP’s **Policy Engine** exists specifically because rules like “exact address only visible to invited users within X hours” and “this role requires vouched + age verification” can’t be hardcoded everywhere.

4.1 Zone access (the hard truth formula)

From the Events spec:

```
[  
Access(u,z,t)=TierOK(u,z)\wedge TicketGrantOK(u,z)\wedge PolicyOK(u,z,t)  
]
```

This matters for creators because **creator work happens in zones** (booths, stage areas, backstage, after-hours nodes).

5) Content creator economics (how creators get paid, mathematically)

5.1 Event revenue engine (canonical math)

Ticketing & Revenue Engine defines the math-level variables and pipeline:

- Gross ticket revenue: $(G = \sum_{i=1}^n p_i)$
- Processor fees: $(P = r_p G + f_p n)$
- Platform fee: $(F_{\text{platform}} = r_{\text{pl}} G)$ (gross-based recommended)
- Sponsor injections: $(S = \sum s_j)$ and **EconomicGross = (G+S)**
- Net door pool: $(\text{NetDoor} = G - P - F_{\text{platform}})$
- Split vector $(W = \{w_v, w_t, w_p, w_r\})$, sum to 1, then:
 - Venue $(= w_v \cdot \text{NetDoor})$
 - Talent/Creator pool $(= w_t \cdot \text{NetDoor})$
 - Promoter pool $(= w_p \cdot \text{NetDoor})$
 - Residual $(= w_r \cdot \text{NetDoor})$

5.2 Promoter/creator attribution (how “creator content” maps to revenue)

The engine defines promoter attribution as: for promoter (k) with ticket set (T_k):

$$\left[\begin{array}{l} \text{Revenue}_k = \sum_{i \in T_k} p_i, \quad \text{Commission}_k = r_k \cdot \text{Revenue}_k \end{array} \right]$$

with an example tiered commission ladder by revenue brackets.

Attribution sources are explicitly allowed as:

- Unique invite links
 - Promoter-specific QR referral
 - Manual allocation
 - Sponsor-allocated guest pools
- ...and **must reconcile deterministically**.

5.3 Attendance bonus (prevents fake hype)

$$\text{AttendanceRate} = \frac{\text{CheckedIn}}{\text{Sold}}$$

$$\text{Bonus pool} = \alpha \cdot \text{NetDoor} \cdot \text{AttendanceRate}$$

This is important: it rewards **real turnout**, not “sold 300 to bots and screenshots.”

5.4 Residual pool + governance ownership (the “invite controllers” layer)

The Ticketing TRD explicitly calls out that **local/sovereign entities may own residual sponsor share**, hold preferred invite allocation, and gain multi-event revenue weighting.

That's your "Tier-3 creator governance" hook: **trusted operators / city cells / sovereign partners** can receive a defined residual stream *because they stabilize continuity*, not because they posted the loudest.

6) The "3-tier content creator system" in WeUP terms (roles × tiers × money)

Think of it as **three creator strata**, each enforced by the *same* tier/trust math above (no separate clout ladder needed):

Creator Tier 1 — Signal Creators (public-facing promoters, street team, influencers)

Method

- They can push discovery **without disclosure** (Ghost Pin / Soft Reveal surfaces).
- They earn via **attribution**, not follower counts.

Math hooks

- Ticket attribution → Commission_k (Section 5.2)
- Attendance bonus exposure if you want: pay higher (r_k) when AttendanceRate is high (optional; consistent with the bonus concept).

Creator Tier 2 — Operators (invited organizers / co-promoters / scene partners)

Method

- They can publish events in trusted contexts, run ticket drops, and operate the event shop layer.
- They can issue **limited invites** (logged).

Math hooks

- Their payouts primarily come from promoter pool ($w_p \cdot \text{NetDoor}$) plus performance bonuses.
- Invite issuance is bounded (cap + logging), preventing spam economies.

Creator Tier 3 — Vouched Circles (trusted creators, crew leads, city cell operators)

Method

- They can access deep reveal, sensitive zones, after-hours reveal gates, and sponsor seeding programs.
- They can be granted governance-linked residual streams (city continuity engine).

Math hooks

- Eligibility is explicitly thresholded:
 - $(T_u(t) \geq \theta_3) + \text{diversity}(k) + \text{optional presence receipts}$
 - Residual share ownership by local/sovereign controllers is a declared future structure.
-

7) Sponsors funding creators (without turning them into billboards)

Sponsors TRD is blunt: **creators are not billboards**.

Sponsors can fund creator seeding programs, opt-in drops, micro-grants, etc., scoped to a “section”:

```
[  
s \in S := (city, \ spot_type, \ zone, \ tier, \ time_window)  
]
```

Coalition Optimization (CRA) — sponsor budget allocation math

A marginal-utility allocation is defined as:

```
[  
\Delta(s) = \frac{w_s \cdot \alpha}{1 + \alpha \cdot B[s]}  
]
```

and iteratively allocates budget to the section with best marginal utility under caps.

Then sponsor-level contributions can be split proportionally by preference weights $(p_{i,s})$.

This becomes a **creator-support engine** because “sections” can include *creator circles* (explicitly present as Opportunity/Program types).

8) “Methods” as an implementable end-to-end creator loop

Here’s the canonical creator loop, stitched directly from the specs:

1. **Creator submits flyer** → Media pipeline parses → creator confirms → event is published (tier-gated).
 2. **Visibility is tier-rendered server-side** (client renders only allowed fields).
 3. **Invites issued** (Tier 2/3 limited + logged) → claimed → tier state updates → ticket availability updates.
 4. **Promotion happens via deterministic attribution** (invite links / QR referrals / manual buckets).
 5. **Door check-in creates Proof-of-Presence** which can unlock gates and bonuses (without surveillance).
 6. **Settlement math runs** (NetDoor, split vector, commissions, attendance bonus, reserves, residual).
 7. **Post-event collapse** keeps accounting + aggregates, purges sensitive traces.
-

9) Optional but on-brand: WLLS for creators (non-screen “content”)

If you want creators to communicate state *in-world* (not through feed posts), WLLS defines the signal grammar:

```
[  
Signal = Color \times Motion \times Intensity \times Rhythm  
]
```

This is perfect for creator operations like: “drop is live,” “pickup queue,” “private mode,” “crew ready,” without exposing identity or demanding phone attention.

If you want the next step to be brutally practical, the missing piece is a **single canonical “Creator Eligibility + Payout Policy” table** (per action: PublishEvent, IssueInvite, StartDrop, JoinSponsorSeeding, etc.) that maps to:

- required tier (A/B/C),
- required trust thresholds (θ),
- required diversity (k),
- required presence window,
- and payout rule hooks (which pool, which formula).
